What do you already know about the following:

- Plotting 2D points?
- Linear equations: $y = 2x + 1$?
- Inequalities: $y \geq x$?

Suppose that we want to determine when z is positive:

$$w_1X_1 + w_2X_2 + b \geq 0$$

Subtract w_2X_2 from both sides to get:

$$w_1X_1 + \cancel{w_2X_2} + b - \cancel{w_2X_2} \geq -w_2X_2$$

When $w_2 > 0$, dividing by $-w_2$ reverses the inequality:

$$\frac{-w_1}{w_2}X_1 - \frac{b}{w_2} \leq X_2$$

Thus, we can study outputs from a single neuron using inequalities!

Afterwards, apply Activation Function: ReLU

$$f(z) = \text{ReLU}(z) = \begin{cases} 0 & \text{if } z < 0 \\ z & \text{if } z \geq 0 \end{cases}$$

Consider a covid test that relies on two measurements to determine whether one has covid.

We measure two numbers (X_1, X_2) from each patient.

We want to plot the measurements as points as follows:

Orange points: Patient has Covid.

Blue points: Patient is normal.

Classification: Linearly Separable Data Categories

Neural Net is a function with an error (or loss)

Easy Intro to
NN

M.S. Pattichis

Background
Check

Plotting
Points

A Single
Neuron

Inequalities

Multiple
Inequalities

Classification

Training and
testing

Assign the following values for the neural network to learn:

+1 for Covid.

-1 for Normal.

We then **want** to train a Neural network so that:

$f(x_1, x_2) = +1$ when (x_1, x_2) is for Covid.

$f(x_1, x_2) = -1$ when (x_1, x_2) is Normal.

When the neural network gets it wrong, it calculates its error (or loss). A simple error is the **squared error**:

$(f(x_1, x_2) - 1)^2$ when (x_1, x_2) is for Covid.

$(f(x_1, x_2) + 1)^2$ when (x_1, x_2) is Normal.

What is the loss when the neural network gets everything right?

Training versus test loss

Classification

Training and
testing

We often want to build a **balanced dataset** with an equal number of members from each category.

Thus, for 100 patients, how many will be Covid cases and how many will be normal?

Furthermore, to measure how well the neural network will perform on new patients, we randomly select a percentage of the patients (e.g., 20%) and save them for **testing** the network **after training**.

A simple setup

Easy Intro to
NN

M.S. Pattichis

Background
Check

Points

A Single
Neuron

Inequalities

Multiple
Inequalities

Classification

Training and
testing

Suppose that we are given 100 points for 50 normals and 50 Covid cases.

We randomly select 20 of them (10 normals + 10 Covid cases) to remove from the dataset for training the neural network. After training, we use these 20 cases to measure the **testing loss**.

We use the 80 remaining ones (40 normals + 40 Covid cases) for training. During training, we use these 80 cases, to measure the **training loss**.

Assigning the training

testing

Very good fit: Both the training and test losses are low.

Underfitting: Training and testing losses are high.

Overfitting: Training loss is low and testing loss is high.
